

RECURRENCE RELATIONS AND VECTOR EQUILIBRIUM PROBLEMS ARISING FROM A MODEL OF NON-INTERSECTING SQUARED BESSEL PATHS

A.B.J. KUIJLAARS AND P. ROMÁN

ABSTRACT. In this paper we consider the model of n non-intersecting squared Bessel processes with parameter α , in the confluent case where all particles start, at time $t = 0$, at the same positive value $x = a$, remain positive, and end, at time $T = t$, at the position $x = 0$. The positions of the paths have a limiting mean density as $n \rightarrow \infty$ which is characterized by a vector equilibrium problem. We show how to obtain this equilibrium problem from different considerations involving the recurrence relations for multiple orthogonal polynomials associated with the modified Bessel functions.

We also extend the situation by rescaling the parameter α , letting it increase proportionally to n as n increases. In this case we also analyze the recurrence relation and obtain a vector equilibrium problem for it.

1. INTRODUCTION AND STATEMENT OF RESULTS

1.1. Introduction. This paper deals with the model, studied in [12], of n non-intersecting squared Bessel paths in the confluent limit where all paths start, at time $t = 0$, at the same positive value $x = a$, remain positive, and end at a later time $t = T$, at the position $x = 0$.

The squared Bessel process is a diffusion process on $[0, \infty)$, depending on a parameter $\alpha > -1$, whose transition probability density is given by

$$P_t^\alpha(x, y) = \frac{1}{2t} \left(\frac{y}{x} \right)^{\frac{\alpha}{2}} e^{-\frac{x+y}{2t}} I_\alpha \left(\frac{\sqrt{xy}}{t} \right), \quad x, y > 0,$$

$$P_t^\alpha(0, y) = \frac{y^\alpha}{(2t)^{\alpha+1} \Gamma(\alpha+1)} e^{-\frac{y}{2t}}, \quad y > 0.$$

Here, I_α denotes the modified Bessel function of the first kind of order α ,

$$I_\alpha(z) = \sum_{k=0}^{\infty} \frac{(z/2)^{2k+\alpha}}{k! \Gamma(k+\alpha+1)}.$$

If we let $n \rightarrow \infty$, and perform an appropriate time scaling $t \mapsto t/(2n)$, $T \mapsto 1/(2n)$, the paths fill out a region in the tx -plane as shown in the left figure in Figure 1. The figure shows a numerical simulation of 50 non-intersecting squared Bessel paths and the boundary of the region filled by the paths. The right part of Figure 1 shows a similar picture where in addition α increases proportionally with n . Since α is a measure for the repulsion from 0 all paths in the right part of

FIGURE 1. Numerical simulation of $n = 50$ non-intersecting squared Bessel paths. The left figure shows n paths with fixed α , and the right figure shows n paths with α increasing proportionally with n .

Figure 1 stay at a positive distance from 0 until the final time $t = 1$. In contrast, in the left part of Figure 1, where α remains fixed, the smallest paths arrive at the hard edge (the wall) at $x = 0$ already at a critical time $t = t^* = a/(1 + a) < 1$, see [12].

The model with fixed α was studied in [12]. One of the results was that for every $t \in (0, 1)$, the positions of the paths at time t have a limiting mean density as $n \rightarrow \infty$, that is characterized by the following vector equilibrium problem (see Theorem 2.4 and the appendix of [12]). The vector equilibrium problem asks to minimize the functional

$$(1.1) \quad \iint \log \frac{1}{|x - y|} d\nu_1(x) d\nu_1(y) + \iint \log \frac{1}{|x - y|} d\nu_2(x) d\nu_2(y) \\ - \iint \log \frac{1}{|x - y|} d\nu_1(x) d\nu_2(y) + \int \left(\frac{x}{t(1 - t)} - \frac{2\sqrt{ax}}{t} \right) d\nu_1(x),$$

over all vectors of measures (ν_1, ν_2) such that

$$(1.2) \quad \text{supp}(\nu_1) \subset [0, \infty), \quad \int d\nu_1 = 1, \quad \text{supp}(\nu_2) \subset (-\infty, 0], \quad \int d\nu_2 = 1/2,$$

and

$$(1.3) \quad \nu_2 \leq \sigma,$$

where σ is the measure on $(-\infty, 0]$ with density

$$(1.4) \quad \frac{d\sigma(x)}{dx} = \frac{\sqrt{a}}{\pi t} |x|^{-1/2}, \quad x \in (-\infty, 0].$$

There is a unique minimizer (ν_1, ν_2) , and the part ν_1 has a density which is the limiting mean density of the positions of the paths at time t . The equilibrium problem depends on the parameters $a > 0$ and $0 < t < 1$ that appear in the energy functional (1.1) as well as in the upper constraint (1.4).

The above equilibrium problem is somewhat unusual since it involves a second measure ν_2 with a constraint σ . It turns out (see [12]) that the constraint is not

active if $t < t^* = a/(a+1)$, that is before the critical time where the smallest paths come to the hard edge. The constraint is active for $t > t^*$.

It is the aim of this paper to give more insight into the nature of the vector equilibrium problem with constraint. We show how it arises from different considerations involving the recurrence relations for multiple orthogonal polynomials associated with modified Bessel functions, see the next section.

We note that a similar vector equilibrium problem with constraint and external field was also found in the context of the Hermitian two-matrix model

$$\frac{1}{Z_n} \exp(-n \operatorname{Tr}(V(M_1) + W(M_2) - \tau M_1 M_2)) dM_1 dM_2$$

where $W(M) = \frac{1}{4}M^4$, see [7]. The vector equilibrium problem now involves three measures, which are located on $\mathbb{R}$, $i\mathbb{R}$ and $\mathbb{R}$, respectively, with a constraint acting on the second measure. The energy functional is similar to (1.1). The polynomials that are connected to this model satisfy a five term recurrence relation. The ideas that are developed in this paper can be extended to analyze this recurrence relation and it is possible to obtain the vector equilibrium problem from it. This will be reported elsewhere.

1.2. Multiple orthogonal polynomials. In [12] it was shown that the positions of the paths at any time $t \in (0, T)$ constitute a multiple orthogonal polynomial (MOP) ensemble associated with the two weight functions

$$(1.5) \quad w_1(x) = x^{\frac{\alpha}{2}} e^{-\frac{Tx}{2t(1-t)}} I_{\alpha} \left(\frac{\sqrt{ax}}{t} \right), \quad w_2(x) = x^{\frac{\alpha+1}{2}} e^{-\frac{Tx}{2t(1-t)}} I_{\alpha+1} \left(\frac{\sqrt{ax}}{t} \right),$$

defined for $x \in (0, +\infty)$. It implies in particular that the ‘average characteristic polynomial’

$$(1.6) \quad B_n(x) = \mathbb{E} \left[\prod_{j=1}^n (x - x_j(t)) \right],$$

where $x_1(t) < x_2(t) < \dots < x_n(t)$ are the positions of the n paths at time t , satisfies the orthogonality relations (assume n is even)

$$(1.7) \quad \int_0^{\infty} B_n(x) x^k w_j(x) dx = 0, \quad \text{for } k = 0, 1, \dots, n/2 - 1, \quad j = 1, 2.$$

The polynomial (1.6) is characterized by a 3×3 matrix valued Riemann-Hilbert problem and the correlation kernel for the MOP ensemble can be written directly in terms of the solution of the Riemann-Hilbert problem. See also [11] for the general notion of a MOP ensemble.

The multiple orthogonal polynomials B_n for the weights (1.5) were studied in detail by Coussemant and Van Assche [4], [5]. They obtained a third order differential equation, which was used in [12]. In addition they also gave an explicit four term recurrence relation

$$(1.8) \quad xB_k(x) = B_{k+1}(x) + b_k B_k(x) + c_k B_{k-1}(x) + d_k B_{k-2}(x)$$

with recurrence coefficients

$$(1.9) \quad \begin{aligned} b_k &= \frac{a(T-t)^2}{T^2} + \frac{2t(T-t)}{T}(2k + \alpha + 1), \\ c_k &= \frac{4at(T-t)^3}{T^3}k + \frac{4t^2(T-t)^2}{T^2}k(k + \alpha), \\ d_k &= \frac{4at^2(T-t)^4}{T^4}k(k-1). \end{aligned}$$

After the rescaling $t \mapsto t/(2n)$, $T \mapsto 1/(2n)$, we obtain a doubly indexed sequence $B_{k,n}$ of polynomials satisfying for each n , the recurrence

$$(1.10) \quad xB_{k,n}(x) = B_{k+1,n}(x) + b_{k,n}B_{k,n}(x) + c_{k,n}B_{k-1,n}(x) + d_{k,n}B_{k-2,n}(x)$$

with recurrence coefficients

$$(1.11) \quad \begin{aligned} b_{k,n} &= a(1-t)^2 + t(1-t)\frac{2k + \alpha + 1}{n}, \\ c_{k,n} &= 2at(1-t)^3\frac{k}{n} + t^2(1-t)^2\frac{k(k + \alpha)}{n^2}, \\ d_{k,n} &= at^2(1-t)^4\frac{k(k-1)}{n^2}. \end{aligned}$$

It is the aim of this paper to obtain the vector equilibrium problem from this recurrence relation. We will show that the measure ν_1 is the limiting zero distribution of the diagonal polynomial $B_{n,n}$ as $n \rightarrow \infty$.

We also consider the following extension of the situation studied in [12]. We rescale the parameter α by letting it increase proportionally to n as n increases. The right figure in Figure 1 shows a numerical simulation of 50 non-intersecting paths for this case. We observe that now the paths stay away from the hard edge $x = 0$. In this case we are also able to analyze the recurrence relation and obtain a vector equilibrium problem from it.

1.3. Polynomials satisfying an m -term recurrence relation. The recurrence coefficients (1.11) are such that whenever $n \rightarrow \infty$, $k \rightarrow \infty$ so that $k/n \rightarrow s$ exists, there is a limit

$$b_{k,n} \rightarrow b(s), \quad c_{k,n} \rightarrow c(s), \quad d_{k,n} \rightarrow d(s)$$

for certain functions $b(s)$, $c(s)$ and $d(s)$.

We will study this situation in the general context of polynomials $P_{k,n}$ depending on two parameters, satisfying for each n , an m -term recurrence relation with varying coefficients

$$(1.12) \quad xP_{k,n}(x) = P_{k+1,n}(x) + b_{k,n}^{(0)}P_{k,n}(x) + b_{k,n}^{(1)}P_{k-1,n}(x) + \cdots + b_{k,n}^{(m-2)}P_{k+2-m,n}(x),$$

with $P_0 \equiv 1$, $P_{-1} \equiv 0, \dots, P_{-m+2} \equiv 0$, where the recurrence coefficients have scaling limits

$$\lim_{k/n \rightarrow s} b_{k,n}^{(j)} = b^{(j)}(s), \quad j = 0, \dots, m-2.$$

for certain functions $b^{(0)}, \dots, b^{(m-2)}$. The notation $\lim_{k/n \rightarrow s}$ that we use here and also later in the paper, means that both $k, n \rightarrow \infty$ with $k/n \rightarrow s$.

We associate with the functions $b^{(j)}$, $j = 0, \dots, m-2$, a family of functions

$$(1.13) \quad A_s(z) = z + b^{(0)}(s) + b^{(1)}(s)z^{-1} + \cdots + b^{(m-2)}(s)z^{-m+2}$$

and the sequence of Toeplitz matrices $(T_n)_n$ where $T_n = T_n(A_s)$ is the $n \times n$ Toeplitz matrix with symbol A_s , defined by

$$(1.14) \quad (T_n(A_s))_{jk} = \begin{cases} 1, & \text{if } k = j + 1, \\ b^{(i)}(s), & \text{if } k = j - i, \quad i = 0, \dots, m-1, \\ 0, & \text{otherwise.} \end{cases}$$

The limiting behavior of the spectrum of $T_n(A_s)$ as $n \rightarrow \infty$ is characterized in terms of the solutions of the algebraic equation $A_s(z) = x$, see [2]. For every $x \in \mathbb{C}$ there exist exactly $m-1$ solutions of the equation $A_s(z) = x$ (assume that $b^{(m-2)}(s) \neq 0$) which we denote by $z_j(x, s)$, $j = 1, \dots, m-1$. We label the solutions by their absolute value so that

$$(1.15) \quad |z_1(x, s)| \geq |z_2(x, s)| \geq \dots \geq |z_{m-1}(x, s)| > 0.$$

We put

$$(1.16) \quad \Gamma_1(s) = \{x \in \mathbb{C} \mid |z_1(x, s)| = |z_2(x, s)|\},$$

which is a finite union of analytic arcs.

We will use the following classical theorem on the behavior of the eigenvalues of $T_n(A_s)$ as $n \rightarrow \infty$.

Theorem 1.1. *As $n \rightarrow \infty$ the eigenvalues of $T_n(A_s)$ accumulate on the contour (1.16).*

The sequence of normalized counting measures of the eigenvalues of $T_n(A_s)$ converges weakly as $n \rightarrow \infty$ to the Borel probability measure μ_1^s on $\Gamma_1(s)$, given by

$$(1.17) \quad d\mu_1^s(x) = \frac{1}{2\pi i} \left(\frac{z'_{1-}(x, s)}{z_{1-}(x, s)} - \frac{z'_{1+}(x, s)}{z_{1+}(x, s)} \right) dx,$$

where $'$ denotes the derivative with respect to x . In (1.17), we have that dx is the complex line element on $\Gamma_1(s)$ and $z_{1\pm}(x, s)$ is the limiting value of $z_1(\tilde{x}, s)$ as $\tilde{x} \rightarrow x$ from the $\pm$ side on each of the arcs in $\Gamma_1(s)$ (the complex line element induces an orientation on $\Gamma_1(s)$ and the $+$ side ($-$ side) is on the left (right) as one traverses $\Gamma_1(s)$ according to the orientation).

Proof. The fact that the eigenvalues accumulate on $\Gamma_1(s)$ was shown by Schmidt and Spitzer [16]. The result about the limit of the normalized eigenvalue counting measures is due to Hirschman [10], see also [2, Chapter 11]. The precise form (1.17) for the limiting measure was given in [6]. $\square$

For later use we also note that by [6, Proposition 4.2],

$$(1.18) \quad \int \frac{d\mu_1^s(y)}{x-y} = \frac{z'_1(x, s)}{z_1(x, s)}, \quad \text{for } x \in \mathbb{C} \setminus \Gamma_1(s),$$

which also characterizes the measure μ_1^s .

Our first result states that, under certain conditions, the polynomials $P_{k,n}$ satisfying the recurrence (1.12) have a limiting zero distribution, which is an average of the measures (1.17). The average is with respect to the parameter s .

Theorem 1.2 is an extension of Theorem 3.1 of [3] to polynomials satisfying an m -term recurrence relation instead of a specific four-term recurrence relation as in [3]. The analogous result for orthogonal polynomials satisfying a three-term recurrence is from [14]. See also [13] and [17] for related results.

Theorem 1.2. *Let for each $n \in \mathbb{N}$, $m-1$ sequences $\{b_{k,n}^{(j)}\}_{k=0}^\infty$, $j = 0, \dots, m-2$, of real coefficients be given and assume that there exist continuous functions $b^{(j)} : [0, \infty) \rightarrow \mathbb{R}$, $j = 0, \dots, m-2$, such that for each $s \geq 0$,*

$$(1.19) \quad \lim_{k/n \rightarrow s} b_{k,n}^{(j)} = b^{(j)}(s), \quad j = 0, \dots, m-2.$$

Let $P_{k,n}$ be the monic polynomials generated by the recurrence (1.12) and suppose that

- (a) *the polynomials $P_{k,n}$ have real and simple zeros $x_1^{k,n} < \dots < x_k^{k,n}$ satisfying for each k and n the interlacing property*

$$x_j^{k+1,n} < x_j^{k,n} < x_{j+1}^{k+1,n}, \quad \text{for } j = 1, \dots, k,$$

- (b) $\Gamma_1(s) \subset \mathbb{R}$ for every $s > 0$, where $\Gamma_1(s)$ is given by (1.16).

Then the normalized zero counting measures $\nu(P_{k,n}) = \frac{1}{k} \sum_{j=1}^k \delta_{x_j^{k,n}}$ have a weak limit as $k, n \rightarrow \infty$ with $k/n \rightarrow \xi > 0$ given by

$$(1.20) \quad \lim_{k/n \rightarrow \xi} \nu(P_{k,n}) = \frac{1}{\xi} \int_0^\xi \mu_1^s ds$$

where μ_1^s is the measure (1.17).

The proof of Theorem 1.2 is given in Section 2.

1.4. Multiple orthogonal polynomials associated with modified Bessel functions. We want to apply Theorem 1.2 to the multiple orthogonal polynomials B_k associated with the modified Bessel function.

1.4.1. Interlacing. The assumption (a) of Theorem 1.2 will be satisfied since we have the following.

Proposition 1.3. *Let $a > 0$, $\alpha > -1$, $0 < t < T$. Then the polynomials B_k generated by the recurrence (1.8) with recurrence coefficients (1.9) have real and simple zeros in $(0, \infty)$ with the interlacing property.*

The proof of Proposition 1.3 is given in Section 3.

1.4.2. First rescaling. In the first rescaling we let t and T depend on n , while α and a remains fixed. We replace

$$t \mapsto t/(2n), \quad T \mapsto 1/(2n)$$

and we obtain the recurrence coefficients as in (1.11). The scaling limits of the recurrence coefficients indeed exist:

$$(1.21) \quad \begin{aligned} \lim_{k/n \rightarrow s} b_{k,n} &= b(s) = a(1-t)^2 + 2st(1-t), \\ \lim_{k/n \rightarrow s} c_{k,n} &= c(s) = 2ast(1-t)^3 + s^2t^2(1-t)^2, \\ \lim_{k/n \rightarrow s} d_{k,n} &= d(s) = as^2t^2(1-t)^4. \end{aligned}$$

Then as in (1.13) we have the associated family of symbols

$$(1.22) \quad A_s(z) = z + b(s) + c(s)z^{-1} + d(s)z^{-2}$$

FIGURE 2. Graph of the curves $\beta(s)$, $\gamma(s)$ and $\eta(s)$ for the first and second rescaling.

and the solutions $z_1(x, s)$, $z_2(x, s)$ and $z_3(x, s)$ of the algebraic equation $A_s(z) = x$. We define $\Gamma_1(s)$ as in (1.16) and similarly

$$(1.23) \quad \Gamma_2(s) = \{x \in \mathbb{C} \mid |z_2(x, s)| = |z_3(x, s)|\}.$$

The symbol (1.22) with the functions $b(s)$, $c(s)$ and $d(s)$ from (1.21) allows for a factorization

$$(1.24) \quad A_s(z) = \frac{(z + a(1-t)^2)(z + st(1-t))^2}{z^2}.$$

From (1.24) we see that A_s has three negative zeros, namely a double zero at $-st(1-t)$ and a simple zero at $-a(1-t)^2$. For the special value

$$s = s^* = \frac{a(1-t)}{t}$$

the three zeros of the symbol coincide.

These facts are used to prove the following.

Proposition 1.4. *For each $s > 0$, we have that $\Gamma_1(s) \subset [0, \infty)$ and $\Gamma_2(s) \subset (-\infty, 0]$. More precisely, there exist $\eta(s) \leq 0 \leq \beta(s) < \gamma(s)$ so that*

$$(1.25) \quad \Gamma_1(s) = [\beta(s), \gamma(s)], \quad \Gamma_2(s) = (-\infty, \eta(s)].$$

In addition we have

- (a) $s \mapsto \gamma(s)$ is strictly increasing for $s > 0$, $\lim_{s \rightarrow 0^+} \gamma(s) = a(1-t)^2$, and $\lim_{s \rightarrow \infty} \gamma(s) = +\infty$,
- (b) $s \mapsto \beta(s)$ is positive and strictly decreasing for $0 < s < s^* = \frac{a(1-t)}{t}$ and $\beta(s) = 0$ for $s \geq s^*$. Furthermore, $\lim_{s \rightarrow 0^+} \beta(s) = a(1-t)^2$,
- (c) $\eta(s) = 0$ for $0 < s \leq s^*$ and $s \mapsto \eta(s)$ is negative, strictly decreasing for $s > s^*$ and $\lim_{s \rightarrow \infty} \eta(s) = -\infty$.

From the proposition it follows that the sets $\Gamma_1(s)$ and $\Gamma_2(s)$ are intervals, and that $\Gamma_1(s)$ is increasing as s increases, while $\Gamma_2(s)$ decreases. See the left part of Figure 2 for an illustrative plot of $\gamma(s)$, $\beta(s)$ and $\eta(s)$, as a function of s .

As a result of Propositions 1.3 and 1.4 we see that the assumptions (a) and (b) of Theorem 1.2 are satisfied, and so for each $\xi > 0$, the weak limit of the normalized zero counting measures of the polynomials $B_{k,n}$ as $k, n \rightarrow \infty$, $k/n \rightarrow \xi$, exists and is given by (1.20).

1.4.3. *Second rescaling.* In the second rescaling we let the parameter α increase as n increases. For this we change the variables t , T and α by

$$t \mapsto t/(2n), \quad T \mapsto 1/(2n), \quad \alpha \mapsto pn$$

with $p > 0$.

The recurrence coefficients (1.9) now have scaling limits that also depend on p . Indeed,

$$\begin{aligned} b(s) &= a(1-t)^2 + 2st(1-t) + t(1-t)p, \\ (1.26) \quad c(s) &= 2ast(1-t)^3 + s^2t^2(1-t)^2 + st^2(1-t)^2p, \\ d(s) &= as^2t^2(1-t)^4. \end{aligned}$$

Now the symbol (1.24) depends on p and we can again explicitly factorize

$$(1.27) \quad A_s(z) = \frac{(z + st(1-t))(z^2 + (1-t)(a(1-t) + (s+p)t)z + ast(1-t)^3)}{z^2}.$$

There are again three negative zeros of the symbol, but now all three zeros are simple.

We again have $\Gamma_1(s)$ and $\Gamma_2(s)$ as in (1.16) and (1.23), and we prove the following.

Proposition 1.5. *Let $p > 0$. Then for each $s > 0$, we have that $\Gamma_1(s) \subset (0, \infty)$ and $\Gamma_2(s) \subset (-\infty, -\frac{p^2t^2}{4a}]$. More precisely, there exist $\eta(s) < 0 < \beta(s) < \gamma(s)$ so that*

$$(1.28) \quad \Gamma_1(s) = [\beta(s), \gamma(s)], \quad \Gamma_2(s) = (-\infty, \eta(s)].$$

In addition we have

- (a) $s \mapsto \gamma(s)$ is strictly increasing for $s > 0$, $\lim_{s \rightarrow 0+} \gamma(s) = (1-t)(a(1-t) + pt)$ and $\lim_{s \rightarrow \infty} \gamma(s) = \infty$,
- (b) $s \mapsto \beta(s)$ is positive and strictly decreasing for $s > 0$ with $\lim_{s \rightarrow 0+} \beta(s) = (1-t)(a(1-t) + pt)$ and $\lim_{s \rightarrow \infty} \beta(s) = 0$,
- (c) $s \mapsto \eta(s)$ is negative and strictly decreasing for $s > 0$ with $\lim_{s \rightarrow 0+} \eta(s) = -\frac{p^2t^2}{4a}$ and $\lim_{s \rightarrow \infty} \eta(s) = -\infty$.

See the right part of Figure 2 for a plot of the functions $\beta(s)$, $\gamma(s)$ and $\eta(s)$ in the case $p = 5$.

Also in the second scaling the assumptions of Theorem 1.2 are satisfied, and again it follows that for each $\xi > 0$, the weak limit of the normalized zero counting measures of the polynomials $B_{k,n}$ as $k, n \rightarrow \infty$, $k/n \rightarrow \xi$, exists and is given by (1.20).

The proof of Propositions 1.4 and 1.5 are given in Section 4.

1.5. **Equilibrium problem.** In both scalings we find for each $\xi > 0$ a probability measure of the form

$$(1.29) \quad \nu_1^\xi = \frac{1}{\xi} \int_0^\xi \mu_1^s ds$$

as the weak limit of the normalized zero counting measures. The main result of the paper is that this measure can also be obtained as the first component of a vector of measures (ν_1^ξ, ν_2^ξ) that satisfies a vector equilibrium problem. For the case $p = 0$ and $\xi = 1$, it reduces to the vector equilibrium problem (1.1)–(1.4) stated in the introduction.

We will use a recent result of Duits and Kuijlaars [6] which in the present context says that the measure μ_1^s that gives the limiting eigenvalue distribution of the Toeplitz matrices with symbol (1.24) is part of a vector (μ_1^s, μ_2^s) that is characterized by a vector equilibrium problem.

The second measure μ_2^s is supported on $\Gamma_2(s)$ (see (1.23)) and is given by

$$(1.30) \quad d\mu_2^s(x) = \frac{1}{2\pi i} \left(\frac{z'_{2-}(x, s)}{z_{2-}(x, s)} - \frac{z'_{2+}(x, s)}{z_{2+}(x, s)} \right) dx$$

for $x \in \Gamma_2(s)$. Then μ_2^s is indeed a positive measure on $\Gamma_2(s)$ with total mass $1/2$.

The result of [6] in this special case is the following.

Theorem 1.6. *For each $s > 0$ we have that the vector (μ_1^s, μ_2^s) is the unique minimizer for the energy functional*

$$(1.31) \quad \iint \log \frac{1}{|x-y|} d\mu_1(x) d\mu_1(y) + \iint \log \frac{1}{|x-y|} d\mu_2(x) d\mu_2(y) - \iint \log \frac{1}{|x-y|} d\mu_1(x) d\mu_2(y)$$

among all vectors (μ_1, μ_2) satisfying $\text{supp}(\mu_j) \subset \Gamma_j(s)$ for $j = 1, 2$, and

$$\int d\mu_1 = 1, \quad \int d\mu_2 = \frac{1}{2}.$$

The measures μ_1^s and μ_2^s satisfy for some constant ℓ^s ,

$$(1.32) \quad 2 \int \log |x-y| d\mu_1^s(y) - \int \log |x-y| d\mu_2^s(y) = \ell^s, \quad x \in \Gamma_1(s),$$

$$(1.33) \quad 2 \int \log |x-y| d\mu_2^s(y) - \int \log |x-y| d\mu_1^s(y) = 0, \quad x \in \Gamma_2(s).$$

The conditions (1.32)–(1.33) are the Euler-Lagrange variational conditions for the vector equilibrium problem.

Recall that we have (1.29) and similarly we put for $\xi > 0$,

$$(1.34) \quad \nu_2^\xi = \frac{1}{\xi} \int_0^\xi \mu_2^s ds.$$

Then ν_2^ξ is a measure on $\bigcup_{s < \xi} \Gamma_2(s) = (-\infty, -p^2 t^2 / 4a]$ with total mass $1/2$. We obtain the vector equilibrium problem for (ν_1^ξ, ν_2^ξ) by integrating the vector equilibrium problem for (μ_1^s, μ_2^s) with respect to s , in particular the variational conditions (1.32)–(1.33). A complication is that the intervals $\Gamma_1(s)$ and $\Gamma_2(s)$ are varying with s . The fact that $\Gamma_1(s)$ is increasing with s induces, after integration, an external field on ν_1^ξ . The fact that $\Gamma_2(s)$ is decreasing as s increases leads to the upper constraint on ν_2^ξ .

Theorem 1.7. *Define*

$$(1.35) \quad V(x) = \int_0^\infty \log \left| \frac{z_1(x, s)}{z_2(x, s)} \right| ds$$

FIGURE 3. Graphs of the densities of σ (dashed) and ν_2^ξ on the negative half line and the density of ν_1^ξ on the positive half line, for the case $p = 0$ and $t < t^*$.

and

$$(1.36) \quad \sigma = \int_0^\infty \mu_2^s ds.$$

Then for every $\xi > 0$, the vector of measures (ν_1^ξ, ν_2^ξ) is the unique minimizer for the energy functional

$$(1.37) \quad \iint \log \frac{1}{|x-y|} d\nu_1(x) d\nu_1(y) + \iint \log \frac{1}{|x-y|} d\nu_2(x) d\nu_2(y) \\ - \iint \log \frac{1}{|x-y|} d\nu_1(x) d\nu_2(y) + \frac{1}{\xi} \int V(x) d\nu_1(x),$$

over all vectors of measures (ν_1, ν_2) such that $\text{supp}(\nu_1) \subset [0, \infty)$, $\int d\nu_1 = 1$, $\text{supp}(\nu_2) \subset (-\infty, 0]$, $\int d\nu_2 = 1/2$, and

$$\nu_2 \leq \frac{1}{\xi} \sigma.$$

The measures ν_1^ξ and ν_2^ξ are characterized by the following variational conditions

$$(1.38) \quad 2 \int \log |x-y| d\nu_1^\xi(y) - \int \log |x-y| d\nu_2^\xi(y) + \frac{1}{\xi} V(x) \begin{cases} = \ell, & \text{for } x \in \text{supp}(\nu_1^\xi), \\ \leq \ell, & \text{for } x \in [0, \infty), \end{cases}$$

for some ℓ , and

$$(1.39) \quad 2 \int \log |x-y| d\nu_2^\xi(y) - \int \log |x-y| d\nu_1^\xi(y) \begin{cases} = 0, & \text{for } x \in \text{supp}(\sigma - \xi \nu_2^\xi), \\ > 0, & \text{for } x \in \mathbb{C} \setminus \text{supp}(\sigma - \xi \nu_2^\xi). \end{cases}$$

The proof of Theorem 1.7 is given in Section 5.

FIGURE 4. Graphs of the densities of σ (dashed) and ν_2^ξ on the negative half line and the density of ν_1^ξ on the positive half line, for the case $p = 0$ and $t > t^*$.

1.6. Evaluation of V and σ . In a final result we are able to evaluate the integrals (1.35) and (1.36) that define V and σ .

Theorem 1.8. *For every $p \geq 0$, we have*

$$(1.40) \quad V(x) = \frac{x}{t(1-t)} - \frac{\sqrt{p^2 t^2 + 4ax}}{t} - p \log \left(\sqrt{p^2 t^2 + 4ax} - pt \right) + \frac{a(1-t)}{t} + p \log(2a(1-t)),$$

and σ is the measure on $(-\infty, 0]$ with density

$$(1.41) \quad \frac{d\sigma(x)}{dx} = \begin{cases} \frac{\sqrt{4a|x| - p^2 t^2}}{2\pi t|x|}, & \text{for } x \in \left(-\infty, -\frac{p^2 t^2}{4a}\right], \\ 0 & \text{for } x \in \left(-\frac{p^2 t^2}{4a}, 0\right]. \end{cases}$$

Note that for $p = 0$, the external field (1.40) is

$$(1.42) \quad V(x) = \frac{x}{t(1-t)} - \frac{2\sqrt{ax}}{t} + \frac{a(1-t)}{t} = \frac{1}{t(1-t)}(\sqrt{x} - \sqrt{a}(1-t))^2$$

and the constraint (1.41) is the measure with density

$$\frac{d\sigma(x)}{dx} = \frac{\sqrt{a}}{\pi t} |x|^{-1/2}, \quad x \in (-\infty, 0].$$

Remark 1.9. Figure 3 shows the graph of the densities of σ , ν_1^ξ and ν_2^ξ in the case $p = 0$ and t below the critical time t^* . This corresponds to the case where the non-intersecting paths did not come to the hard edge. The constraint σ is not active and ν_1^ξ is supported on an interval which is at a positive distance from zero. Figure 4 illustrates the case $p = 0$ for $t > t^*$. Here the constraint σ is active in an interval.

Figure 5 shows the densities of σ , ν_1^ξ and ν_2^ξ for $p > 0$. For all values of t , the constraint σ is active in some interval and ν_1^ξ is supported on an interval which is at a positive distance from zero.

FIGURE 5. Graphs of the densities of σ (dashed) and ν_2^ξ on the negative real line and the density of ν_1^ξ on the positive real line for $p > 0$.

Remark 1.10. It was pointed out that if we let $n \rightarrow \infty$, the paths fill out a region in the tx -plane. This can be observed in the left figure of Figure 1 for the case $p = 0$ and in the right figure of Figure 1 for the case $p > 0$. The region filled by the paths, for a fixed time $t \in [0, 1]$, is exactly the interval $[\beta(1), \gamma(1)]$. We can obtain $\beta(1)$ and $\gamma(1)$ by computing the zeros of the discriminant of the polynomial $z^2 A_1(z) - z^2 x$ with respect to z , which is the following algebraic equation of degree three in x :

$$4ax^3 - [8a^2(1-t)^2 + 4at(1-t)(2p+5) - t^2(p+1)^2]x^2 + (1-t)[4a^3(1-t)^3 + 4a^2t(1-t)^2(2p-3) + 2at^2(1-t)(p^2+p+6) - 2t^3(p+2)(p+1)^2]x + p^2t^2(1-t)^2[a^2(1-t)^2 + 2at(1-t)(p-1) + t^2(p+1)^2] = 0.$$

If $p = 0$ then the algebraic equation reduces to

$$(1.43) \quad x(4ax^2 - x(8a^2(1-t)^2 + 20at(1-t) - t^2) + 4(1-t)(a(1-t) - t)^3) = 0.$$

We can compute explicit expressions for the solutions in this case

$$\begin{aligned} x_1(t) &= 0, \\ x_2(t) &= \frac{1}{8a} (8a^2(1-t)^2 - t(t - 20a(1-t)) - \sqrt{t(t + 8a(1-t))^3}), \\ x_3(t) &= \frac{1}{8a} (8a^2(1-t)^2 - t(t + 20a(1-t)) + \sqrt{t(t + 8a(1-t))^3}). \end{aligned}$$

Remark 1.11. If we let $a \rightarrow 0$ and $s = 1$, then the symbol (1.27) becomes

$$\frac{(1 + zt(1-t))^2}{z^2} + \frac{pt(1-t)(1 + zt(1-t))}{z}.$$

FIGURE 6. Numerical simulation of 50 non-intersecting paths for $a = 0$ and $p = 0$ (left), $p > 0$ (right).

The solution $z_3(x, 1)$ tends to zero as $a \rightarrow 0$. On the other hand, the solutions $z_1(x, 1)$ and $z_2(x, 1)$ have limits (with appropriate choice of $\pm$ -sign)

$$\begin{aligned} z_1(x) &= -\frac{1}{2}t(1-t)(p+2) + \frac{x}{2} + \frac{1}{2}((x - \rho_1(t))(x - \rho_2(t)))^{1/2}, \\ z_2(x) &= -\frac{1}{2}t(1-t)(p+2) + \frac{x}{2} - \frac{1}{2}((x - \rho_1(t))(x - \rho_2(t)))^{1/2}, \end{aligned}$$

as $a \rightarrow 0$, where

$$\rho_1(t) = t(1-t)(p+2-2\sqrt{p+1}), \quad \rho_2(t) = t(1-t)(p+2+2\sqrt{p+1}).$$

One can show that ν_1 is the Marchenko-Pastur distribution, see e.g. [9], with density

$$\frac{d\nu_1(x)}{dx} = \frac{\sqrt{(\rho_2(t) - x)(x - \rho_1(t))}}{2\pi t(1-t)x}, \quad x \in [\rho_1(t), \rho_2(t)].$$

Figure 6 shows simulations of 50 non-intersecting squared Bessel paths for the case $a = 0$ and the boundaries $\rho_1(t)$ and $\rho_2(t)$ of the region filled by the paths as $n \rightarrow \infty$.

The rest of the paper is devoted to the proofs of the theorems and propositions stated above. Theorem 1.2 is proved in Section 2, Proposition 1.3 in Section 3, Propositions 1.4 and 1.5 in Section 4, Theorem 1.7 in Section 5, and finally Theorem 1.8 is proved in Section 6.

2. PROOF OF THEOREM 1.2

Before proving Theorem 1.2 we will state a result concerning ratio asymptotics of polynomials satisfying a recurrence relation (1.12) with varying recurrence coefficients.

The following lemma will be used in the proofs of Theorem 1.2 and Lemma 2.2.

Lemma 2.1. *Suppose that the zeros of the monic polynomials P_k and P_{k+1} , with degrees k and $k+1$, respectively, are simple and real, lie in an interval $[-R, R]$ for*

some $R > 0$, and are interlacing. Then we have

$$(2.1) \quad \left| \frac{P_k(z)}{P_{k+1}(z)} \right| \leq \frac{1}{\text{dist}(z, [-R, R])} \quad \text{for } z \in \mathbb{C} \setminus [-R, R],$$

$$(2.2) \quad \left| \frac{P_k(z)}{P_{k+1}(z)} \right| \geq \frac{1}{2|z|} \quad \text{for } |z| > R,$$

$$(2.3) \quad \left| \left(\frac{P_k(z)}{P_{k+1}(z)} \right)' \right| \leq \frac{1}{\text{dist}(z, [-R, R])^2} \quad \text{for } z \in \mathbb{C} \setminus [-R, R].$$

Proof. Inequalities (2.1) and (2.2) can be found in [14, Lemma 2.2]. The proof of (2.3) is similar to that of (2.1). $\square$

We consider the doubly indexed sequences of polynomials $\{P_{k,n}\}$ generated by the m -term recurrence relation (1.12) and we assume that the recurrence coefficients have scaling limits

$$\lim_{k/n \rightarrow s} b_{k,n}^{(j)} = b^{(j)}(s).$$

Lemma 2.2. *Under the assumptions of Theorem 1.2 we have that for each $s > 0$, there exists $R > 0$ so that all zeros of $P_{k,n}$ belong to $[-R, R]$ whenever $k \leq (s+1)n$. Moreover,*

$$(2.4) \quad \lim_{k/n \rightarrow s} \frac{P_{k+1,n}(x)}{P_{k,n}(x)} = z_1(x, s),$$

uniformly on compact subsets of $\mathbb{C} \setminus [-R, R]$.

Proof. Fix $s > 0$. The convergence (1.19) imply that the recurrence coefficients are uniformly bounded if k/n is restricted to compact subsets of $[0, \infty)$. So, the number R defined by

$$(2.5) \quad R := \sup\{1 + |b_{k,n}^{(0)}| + |b_{k,n}^{(1)}| + \cdots + |b_{k,n}^{(m-2)}| \mid k \leq (s+1)n\}$$

is finite.

By the recurrence (1.12) we have $P_{k,n}(x) = \det(zI_k - M_{k,n})$ where $M_{k,n}$ is the matrix

$$(2.6) \quad M_{k,n} = \begin{pmatrix} b_{0,n}^{(0)} & 1 & 0 & & & & \\ b_{1,n}^{(1)} & b_{1,n}^{(0)} & 1 & 0 & & & \\ \vdots & & \ddots & 1 & \ddots & & \\ b_{m-2,n}^{(m-2)} & & & \ddots & \ddots & \ddots & \\ 0 & \ddots & & & \ddots & \ddots & 0 \\ & \ddots & \ddots & & & \ddots & 1 \\ & & 0 & b_{k-1,n}^{(m-2)} & \cdots & \cdots & b_{k-1,n}^{(0)} \end{pmatrix}.$$

The zeros of $P_{k,n}$ are equal to the eigenvalues of $M_{k,n}$, and their absolute values are bounded by the maximum absolute row sum of $M_{k,n}$. Therefore, by the definition (2.5), if $k \leq (s+1)n$ then the zeros of $P_{k,n}$ lie in the interval $[-R, R]$.

We consider the family of functions

$$(2.7) \quad \mathcal{H} = \left\{ \frac{P_{k+1,n}}{P_{k,n}} \mid k, n \in \mathbb{N}, k+1 \leq (s+1)n \right\}.$$

Because of the assumption (a) in Theorem 1.2 we can apply Lemma 2.1 to $P_{k,n}$ and $P_{k+1,n}$. It follows from (2.1), (2.2) and (2.7) that the family $\mathcal{H}$ is a normal family (in the sense of Montel) on $\mathbb{C} \setminus [-R, R]$.

Using induction on l , we will show the following.

Claim: For each $l \geq 0$, the following holds. If $\{k_i\}_i, \{n_i\}_i$ are sequences of non-negative integers with $k_i, n_i \rightarrow \infty, k_i/n_i \rightarrow s$ as $i \rightarrow \infty$, so that

$$(2.8) \quad f(x) := \lim_{i \rightarrow \infty} \frac{P_{k_i+1, n_i}(x)}{P_{k_i, n_i}(x)}$$

exists for $|x| > R$, then

$$(2.9) \quad f(x) = z_1(x, s) + \mathcal{O}(x^{-l})$$

as $x \rightarrow \infty$.

We have $z_1(x, s) = x + \mathcal{O}(1)$, as $x \rightarrow \infty$, and so it is clear that (2.9) holds for $l = 0$.

Now assume that the claim holds for $l \geq 0$. Let $\{k_i\}$ and $\{n_i\}$ be as in the claim. Since $k_i/n_i \rightarrow s$ as $i \rightarrow \infty$, we may assume that $k_i \leq (s+1)n_i$ for every i . For $j = 0, \dots, m-2$, we then have that

$$\frac{P_{k_i+1-j, n_i}}{P_{k_i-j, n_i}}$$

belongs to the family $\mathcal{H}$. Since it is a normal family, we may assume, by passing to a subsequence if necessary, that

$$(2.10) \quad f^{(j)}(x) = \lim_{i \rightarrow \infty} \frac{P_{k_i+1-j, n_i}(x)}{P_{k_i-j, n_i}(x)}$$

exists for $x \in \overline{\mathbb{C}} \setminus [-R, R]$ and $j = 0, \dots, m-2$.

Now we divide the recurrence (1.12) by $P_{k,n}$, and replace k and n by k_i and n_i , to obtain for each j ,

$$x = \frac{P_{k_i+1, n_i}(x)}{P_{k_i, n_i}(x)} + b_{k_i, n_i}^{(0)} + \sum_{j=1}^{m-2} b_{k_i, n_i}^{(j)} \frac{P_{k_i-j, n_i}(x)}{P_{k_i, n_i}(x)}.$$

We let $i \rightarrow \infty$, where we note that by (1.19)

$$b_{k_i, n_i}^{(j)} \rightarrow b^{(j)}(s)$$

and by (2.10)

$$\frac{P_{k_i-j, n_i}(x)}{P_{k_i, n_i}(x)} \rightarrow \left[f^{(1)}(x) \cdots f^{(j)}(x) \right]^{-1}$$

for $x \in \overline{\mathbb{C}} \setminus [-R, R]$ and $j = 1, \dots, m-2$. Thus

$$x = f(x) + b^{(0)}(s) + \sum_{j=1}^{m-2} b^{(j)}(s) \left[f^{(1)}(x) \cdots f^{(j)}(x) \right]^{-1}.$$

for all $x \in \mathbb{C} \setminus [-R, R]$.

Now by the induction hypothesis we have for $j = 0, \dots, m-2$,

$$f^{(j)}(x) = z_1(x, s) + \mathcal{O}(x^{-l}) = z_1(x, s) (1 + \mathcal{O}(x^{-l-1})) \quad \text{as } x \rightarrow \infty.$$

and so

$$\begin{aligned}
f(x) &= x - b^{(0)}(s) - \sum_{j=1}^{m-2} b^{(j)}(s) \left[f^{(1)}(x) \cdots f^{(j)}(x) \right]^{-1} \\
&= x - b^{(0)}(s) - \sum_{j=1}^{m-2} b^{(j)}(s) z_1(x, s)^{-j} (1 + \mathcal{O}(x^{-l-1})) \\
&= x - b^{(0)}(s) - \sum_{j=1}^{m-2} b^{(j)}(s) z_1(x, s)^{-j} + \mathcal{O}(x^{-l-2}).
\end{aligned}$$

Since $z_1(x, s)$ is a solution of $A_s(z) = x$, we have

$$x - b^{(0)}(s) - \sum_{j=1}^{m-2} b^{(j)}(s) z_1(x, s)^{-j} = z_1(x, s)$$

and so we obtain

$$f(x) = z_1(x, s) + \mathcal{O}(x^{-l-2})$$

as $x \rightarrow \infty$, which proves (2.9) for $l + 2$.

The claim now proved, we finally show how the lemma follows from the claim. First note that f is analytic in $\mathbb{C} \setminus [-R, R]$ and $x \mapsto z_1(x, s)$ is defined, analytic and non-zero in $\mathbb{C} \setminus \Gamma_1(s)$. Thus, if (2.9) holds for every l , then clearly $f(x) = z_1(x, s)$ for x in a neighborhood of ∞ in the x -plane, and by analyticity the equality extends to $\mathbb{C} \setminus ([-R, R] \cup \Gamma_1(s))$. Next, recall the assumption (b) in Theorem 1.2, which says that $\Gamma_1(s) \subset \mathbb{R}$. Then it easily follows by its definition that $z_1(x, s)$ cannot possibly have an analytic continuation from $\mathbb{C} \setminus \Gamma_1(s)$ to a larger set. Thus $\Gamma_1(s) \subset [-R, R]$ and it follows that

$$(2.11) \quad \lim_{i \rightarrow \infty} \frac{P_{k_i+1, n_i}(x)}{P_{k_i, n_i}(x)} = z_1(x, s), \quad x \in \mathbb{C} \setminus [-R, R],$$

for all sequences $\{k_i\}, \{n_i\}$ as in the statement of (2.7).

Then by a standard normal families argument (recall that the family $\mathcal{H}$ is a normal family) (2.4) follows. $\square$

Proof of Theorem 1.2. Let $\xi > 0$, and take $0 \leq s \leq 1$. From Lemma 2.2, there exists $R > 0$ such that all zeros of $P_{k,n}$ belong to $[-R, R]$. For $k \in \mathbb{N}$, we use $\lfloor sk \rfloor$ to denote the greatest integer less than or equal to sk . We observe that

$$\begin{aligned}
\frac{1}{k} \frac{P'_{k,n}(x)}{P_{k,n}(x)} &= \frac{1}{k} \sum_{j=0}^{k-1} \left(\frac{P'_{j+1,n}(x)}{P_{j+1,n}(x)} - \frac{P'_{j,n}(x)}{P_{j,n}(x)} \right) \\
(2.12) \quad &= \int_0^1 \left(\frac{P'_{\lfloor sk \rfloor + 1, n}(x)}{P_{\lfloor sk \rfloor + 1, n}(x)} - \frac{P'_{\lfloor sk \rfloor, n}(x)}{P_{\lfloor sk \rfloor, n}(x)} \right) ds.
\end{aligned}$$

By taking the logarithmic derivative of (2.4) and using (1.18) we obtain

$$(2.13) \quad \lim_{k/n \rightarrow \xi} \left(\frac{P'_{\lfloor sk \rfloor + 1, n}(x)}{P_{\lfloor sk \rfloor + 1, n}(x)} - \frac{P'_{\lfloor sk \rfloor, n}(x)}{P_{\lfloor sk \rfloor, n}(x)} \right) = \frac{z'_1(x, s\xi)}{z_1(x, s\xi)} = \int \frac{d\mu_1^{s\xi}(y)}{x - y},$$

uniformly on compact subsets of $\mathbb{C} \setminus [-R, R]$. From (2.2) and (2.3) in Lemma 2.1 we obtain

$$(2.14) \quad \left| \frac{P'_{[sk]+1,n}(x)}{P_{[sk]+1,n}(x)} - \frac{P'_{[sk],n}(x)}{P_{[sk],n}(x)} \right| = \left| \left(\frac{P_{[sk],n}(x)}{P_{[sk]+1,n}(x)} \right)' \right| \left| \frac{P_{[sk]+1,n}(x)}{P_{[sk],n}(x)} \right| \leq \frac{2|z|}{\text{dist}(z, [-R, R])^2}.$$

for $|z| > R$. Therefore we may apply Lebesgue's dominated convergence theorem and it follows by (2.12) and (2.13)

$$\lim_{k/n \rightarrow \xi} \frac{1}{k} \frac{P'_{k,n}(x)}{P_{k,n}(x)} = \int_0^1 \int \frac{d\mu_1^{s\xi}(y)}{x-y} ds = \frac{1}{\xi} \int_0^\xi \int \frac{d\mu_1^s(y)}{x-y} ds.$$

Therefore we have that

$$\lim_{k/n \rightarrow \xi} \frac{1}{k} \frac{P'_{k,n}(x)}{P_{k,n}(x)} = \int \frac{1}{\xi} \int_0^\xi \frac{d\mu_1^s(y)}{x-y} ds,$$

for all $x \in \mathbb{C} \setminus [-R, R]$. This gives, by a standard argument, see [15], that the polynomials $P_{k,n}$ have

$$\nu_1^\xi = \frac{1}{\xi} \int_0^\xi \mu_1^s(\lambda) ds,$$

as limiting zero distribution as $k/n \rightarrow \xi$. $\square$

3. PROOF OF PROPOSITION 1.3

In [4] it is proved that the weights (w_1, w_2) from (1.5) are such that there exist discrete measures σ_1 and σ_2 on $(-\infty, 0]$ such that

$$\frac{w_2(x)}{w_1(x)} = x \int_{-\infty}^0 \frac{d\sigma_1(t)}{x-t}, \quad \frac{w_1(x)}{w_2(x)} = \int_{-\infty}^0 \frac{d\sigma_2(t)}{x-t}, \quad x > 0.$$

From this it is shown in [4, Theorem 4] that the weights (w_1, w_2) form an AT-system on $[0, \infty)$, which means that for any $n_1, n_2 \in \mathbb{N}$, the set of real valued functions

$$\mathcal{F}_{n_1, n_2} = \{w_1(x), xw_1(x), \dots, x^{n_1}w_1(x), w_2(x), xw_2(x), \dots, x^{n_2}w_2(x)\},$$

is a Chebyshev system on $(0, \infty)$ i.e., every linear combination $\sum_{k=1}^{n_1+n_2+2} a_k \varphi_k$, with $\varphi_k \in \mathcal{F}_{n_1, n_2}$, $\varphi_k \neq \varphi_{k'}$ if $k \neq k'$, and $(a_1, \dots, a_{n_1+n_2+2}) \neq (0, \dots, 0)$, has at most $n_1 + n_2 + 1$ zeros in $(0, \infty)$.

A consequence of this result is that for every $n_1, n_2 \in \mathbb{N}$ there is a unique monic polynomial B_{n_1, n_2} of degree $n_1 + n_2$ satisfying the orthogonality conditions

$$(3.1) \quad \int_0^\infty B_{n_1, n_2}(x) x^k w_j(x) dx = 0, \quad \text{for } k = 0, 1, \dots, n_j - 1, \quad j = 1, 2.$$

The polynomial B_{n_1, n_2} has exactly $n_1 + n_2$ simple zeros in $(0, \infty)$, see e.g. [19]. Comparing (3.1) with (1.5) we see that $B_n = B_{n_1, n_2}$ with $n_1 = n_2 = n/2$ if n is even, and $n_1 = (n+1)/2$, $n_2 = (n-1)/2$ if n is odd.

The interlacing of zeros now follows from Lemma 2.3 and Remark 2.1 of [1]. Indeed there it is shown that for any n_1, n_2 the zeros of B_{n_1, n_2} are interlaced with those of B_{n_1+1, n_2} and with those of B_{n_1, n_2+1} .

For convenience of the reader, we give the proof of interlacing following [1] (see also [8, Lemma 5 and Corollary 1] for a different approach). We show that the zeros of B_{n_1, n_2} interlace with those of B_{n_1+1, n_2} , the proof for B_{n_1, n_2+1} being similar.

FIGURE 7. The graph of $A_s(z)$ (1.27), $z \in \mathbb{R}$, for $p > 0$.

Let us consider a polynomial $P = aB_{n_1, n_2} + bB_{n_1+1, n_2}$ with $(a, b) \neq (0, 0)$. Let us assume that P has a double real zero at $\zeta \in \mathbb{R}$. Then

$$(3.2) \quad P(x) = aB_{n_1, n_2}(x) + bB_{n_1+1, n_2}(x) = (x - \zeta)^2 R(x), \quad \deg R \leq n_1 + n_2 - 1.$$

From the orthogonality conditions (3.1) it follows that R satisfies

$$(3.3) \quad \int_0^\infty R(x) x^k (x - \zeta)^2 w_j(x) dx = \int_0^\infty (aB_{n_1, n_2}(x) + bB_{n_1+1, n_2}(x)) w_j(x) dx = 0 \quad \text{for } k = 0, \dots, n_j - 1, \quad j = 1, 2.$$

Thus R has multiple orthogonality conditions with respect to the weights $(\tilde{w}_1, \tilde{w}_2)$ where

$$\tilde{w}_1(x) = (x - \zeta)^2 w_1(x), \quad \text{and} \quad \tilde{w}_2(x) = (x - \zeta)^2 w_2(x).$$

By the same reasoning as in [4] it follows that $(\tilde{w}_1, \tilde{w}_2)$ is also an AT system on $[0, \infty)$. It follows that any monic polynomial R that satisfies (3.3) should have degree $\geq n_1 + n_2$, and this is a contradiction.

Therefore the polynomial P has only simple zeros in $\mathbb{R}$. This means that for every fixed $x \in \mathbb{R}$, the linear system

$$\begin{pmatrix} B_{n_1, n_2}(x) & B_{n_1+1, n_2}(x) \\ B'_{n_1, n_2}(x) & B'_{n_1+1, n_2}(x) \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

has only the trivial solution $a = b = 0$. Then the determinant is non-zero

$$B_{n_1, n_2}(x)B'_{n_1+1, n_2}(x) - B_{n_1+1, n_2}(x)B'_{n_1, n_2}(x) \neq 0, \quad x \in \mathbb{R},$$

which readily implies that B_{n_1, n_2} has opposite signs at consecutive zeros of B_{n_1+1, n_2} . It follows that between two consecutive zeros of B_{n_1+1, n_2} there is at least one zero of B_{n_1, n_2} , and this proves the interlacing of zeros. $\square$

4. PROOF OF PROPOSITIONS 1.4 AND 1.5

Propositions 1.4 and 1.5 will be proved simultaneously. First of all we observe that the symbol allows for a factorization

$$(4.1) \quad A_s(z) = \frac{(z - r_1)(z - r_2)(z - r_3)}{z^2}, \quad \text{with } r_1, r_2, r_3 < 0,$$

see (1.24) for the case $p = 0$, and (1.27). We order the roots so that

$$r_1 \leq r_2 \leq r_3 < 0.$$

If $p > 0$, then it is elementary to check from (1.27) that all zeros are distinct. Figure 7 shows the plot of $A_s(z)$ for the case $p > 0$. If $p = 0$, then it follows from (1.24) that

$$\begin{aligned} r_1 = r_2 < r_3 < 0, & \quad \text{if } st < a(1 - t), \\ r_1 = r_2 = r_3 < 0, & \quad \text{if } st = a(1 - t), \\ r_1 < r_2 = r_3 < 0, & \quad \text{if } st > a(1 - t). \end{aligned}$$

These three cases are illustrated in Figures 8, 9 and 10, respectively.

The derivative of $A_s(z)$,

$$A'_s(z) = 1 - c(s)z^{-2} - 2d(s)z^{-3},$$

has three roots in the complex plane. From Figures 7, 8, 9, and 10 we see that all zeros of A'_s are real. We denote the zeros of $A'(z)$ by y_1, y_2 and y_3 so that

$$y_1 \leq y_2 < 0 < y_3,$$

as indicated in the figures. The equality $y_1 = y_2$ only holds if $p = 0$ and $s = s^*$ as in Figure 9. To indicate the dependence on s we also write $y_1(s), y_2(s)$ and $y_3(s)$.

Before proving Propositions 1.4 and 1.5 we first need two lemmas. The proofs of these lemmas only use the fact that the zeros r_j of the symbol A_s are strictly negative.

Lemma 4.1. *Assume that $z_1, z_2 \in \mathbb{C}$ are such that $z_1 \neq z_2$, $|z_1| = |z_2|$ and $A_s(z_1) = A_s(z_2) = x$. Then $z_1 = \bar{z}_2$ and $x \in \mathbb{R}$.*

Proof. The complex numbers z_1 and z_2 lie in a circle of radius $\rho = |z_1| = |z_2|$ centered at the origin in the complex plane. Then from (4.1) we have

$$|A_s(z)| = \frac{\text{dist}(z, r_1) \text{dist}(z, r_2) \text{dist}(z, r_3)}{\rho^2}, \quad \text{if } |z| = \rho.$$

Since all $r_j < 0$, it follows that

$$[-\pi, \pi] \rightarrow \mathbb{R} : \theta \mapsto |A_s(\rho e^{i\theta})|$$

is an even function which is strictly decreasing as θ increases from 0 to π .

Thus equality

$$|A_s(\rho e^{i\theta_1})| = |A_s(\rho e^{i\theta_2})|,$$

with $\theta_{1,2} \in [-\pi, \pi]$ and $\theta_1 \neq \theta_2$ can only occur if $\theta_2 = -\theta_1$. Then it follows from the assumptions of the lemma, that $z_1 = \bar{z}_2$, and

$$x = A_s(z_1) = \overline{A_s(\bar{z}_1)} = \overline{A_s(z_2)} = \bar{x}$$

so that $x \in \mathbb{R}$. □

FIGURE 8. Graph of $A_s(z)$ (1.24), $z \in \mathbb{R}$, in the case $p = 0$, $s < s^*$.

Lemma 4.2. *For each $s > 0$ we have $\Gamma_1(s) \cup \Gamma_2(s) \subset \mathbb{R}$. Moreover, if $p > 0$ or if $p = 0$ and $s \neq s^* = a(1-t)/t$, then $\Gamma_1(s) \cap \Gamma_2(s) = \emptyset$. On the other hand, if $p = 0$ and $s = s^*$, then $\Gamma_1(s) \cap \Gamma_2(s) = \{0\}$.*

Proof. If $x \in \Gamma_1(s) \cup \Gamma_2(s)$ and $A_s(z) - x$ has a double root, then there exists $z_1 \in \mathbb{C}$ such that $A_s(z_1) = x$ and $A'_s(z_1) = 0$. Since all zeros of $A'_s(z)$ are real, it follows that $z_1 \in \mathbb{R}$.

If $x \in \Gamma_1(s) \cup \Gamma_2(s)$ and $A_s(z) - x$ does not have a double root, then there exist $z_1, z_2 \in \mathbb{C}$ such that $z_1 \neq z_2$, $|z_1| = |z_2|$ and $x = A_s(z_1) = A_s(z_2)$. Lemma 4.1 says that $x \in \mathbb{R}$. This proves that $\Gamma_1(s) \cup \Gamma_2(s) \subset \mathbb{R}$.

If $x \in \Gamma_1(s) \cap \Gamma_2(s)$, and $s \neq s^*$ if $p = 0$, then there exist three solutions of $A_s(z) = x$. One negative solution $z_1 < 0$ and two complex conjugated solutions z_2 and $\bar{z}_2$ (see Figures 7, 8, 10). Moreover $z_1 \neq z_2$ and $z_1 \neq \bar{z}_2$. Now $|z_1| = |z_2|$ ($x \in \Gamma_1(s)$) and $A_s(z_1) = A_s(z_2)$. Therefore we can apply Lemma 4.1 and we obtain $z_1 = \bar{z}_2$ which is a contradiction. Then $\Gamma_1(s) \cap \Gamma_2(s) = \emptyset$.

The fact that $\Gamma_1(s^*) \cap \Gamma_2(s^*) = \{0\}$, if $p = 0$, follows directly from Figure 9, by observing that $z = -a(1-t)^2$ is a triple root of $A_s(z)$. $\square$

Proof of Propositions 1.4 and 1.5. If $p > 0$ then there are three local extrema of $A_s(z)$, namely $\beta(s), \gamma(s), \eta(s)$, such that

$$\eta(s) < 0 < \beta(s) < \gamma(s).$$

If $x \in (\eta(s), \beta(s)) \cup (\gamma(s), \infty)$, then there exist three different real solutions of $A_s(z) = x$. It is easily seen that these solutions also differ in absolute value (Figure 7, and Lemma 4.1 if $x \in (\gamma(s), \infty)$). On the other hand, there is one real and two complex conjugated solutions whenever $x \in (-\infty, \eta(s)] \cup [\beta(s), \gamma(s)]$. Therefore

$$\Gamma_1(s) \cup \Gamma_2(s) \subset (-\infty, \eta(s)] \cup [\beta(s), \gamma(s)].$$

We have that $A_s(z) = \gamma(s)$ has a double root $y_3 = y_3(s) > 0$ and one negative root whose absolute value is less than $y_3(s)$. Thus $\gamma(s) \in \Gamma_1(s)$. Also $\beta(s) \in \Gamma_1(s)$. Now the fact that $\Gamma_1(s)$ is connected (see [18], [2, Theorem 11.19]) says that $\Gamma_1(s) =$

 FIGURE 9. Graph of $A_s(z)$ (1.24), $z \in \mathbb{R}$, in the case $p = 0$, $s = s^*$.

$[\beta(s), \gamma(s)]$. On the other hand $A_s(z) = \eta(s)$ has a double root at $y_2(s) < 0$ and a negative root whose absolute value is larger than $|y_2(s)|$. Therefore $\eta_2(s) \in \Gamma_2(s)$ and $\Gamma_2(s) = (-\infty, \eta(s)]$.

The case $p = 0$ follows analogously by studying Figures 8, 9, and 10 whenever $st < a(1-t)$, $st = a(1-t)$ or $st > a(1-t)$, respectively. We deduce from Figure 8 that $\eta(s) = 0$ for $st < a(1-t)$. On the other hand, Figure 10 shows that $\beta(s) = 0$ if $st > a(1-t)$.

We shall prove that $\gamma(s)$ is an increasing function. The monotonicity of $\beta(s)$ and $\eta(s)$ is proved with similar considerations. Observe that the function

$$B(z, s) = A_s(sz) = \frac{(sz + a(1-t)^2)(z + t(1-t))^2}{z^2} + \frac{pt(1-t)(z + t(1-t))}{z},$$

as a function of z , has a local minimum at $y_3(s)/s$ and

$$\gamma(s) = A_s(y_3(s)) = B(y_3(s)/s, s).$$

If we take the partial derivative of $B(z, s)$ with respect to s we obtain

$$\frac{\partial B(z, s)}{\partial s} = \frac{(z + t(1-t))^2}{z}.$$

which is positive for all $z > 0$. Then the fact that $z \mapsto B(z, s)$ has a minimum at $y_3(s)/s$ implies that

$$\gamma'(s) = \frac{\partial B(y_3(s)/s, s)}{\partial z} \frac{(y_3'(s)s - y_3(s))}{s^2} + \frac{\partial B(y_3(s)/s, s)}{\partial s} = \frac{\partial B(y_3(s)/s, s)}{\partial s} > 0,$$

and therefore $\gamma(s)$ is increasing for all $s > 0$.

FIGURE 10. Plots of $A_s(z)$ (1.24), $z \in \mathbb{R}$, in the case $p = 0$, $s > a(1-t)/t$.

If $p > 0$, it is a straightforward computation that $y_1(s)$, $y_2(s)$ and $y_3(s)$ have the following behavior as $s \rightarrow \infty$

$$\begin{aligned} y_1(s) &= st(1-t) + \mathcal{O}(1), \\ y_2(s) &= -2a(1-t)^2 + \mathcal{O}(s^{-1}), \\ y_3(s) &= -st(1-t) - \frac{1}{2}t(1-t)p + \mathcal{O}(s^{-1}). \end{aligned}$$

Then we obtain

$$\begin{aligned} \gamma(s) &= A_s(y_3(s)) = 4st(1-t) + \mathcal{O}(1), \\ \beta(s) &= A_s(y_2(s)) = \frac{1}{4}tp^2(1-t)s^{-1} + \mathcal{O}(s^{-2}), \\ \eta(s) &= A_s(y_1(s)) = -\frac{s^2t^2}{4a} + \mathcal{O}(s), \end{aligned}$$

as $s \rightarrow \infty$. This proves the limits

$$\lim_{s \rightarrow \infty} \beta(s) \rightarrow 0, \quad \lim_{s \rightarrow \infty} \gamma(s) = \infty, \quad \lim_{s \rightarrow \infty} \eta(s) = -\infty,$$

and completes the proof of the propositions. $\square$

5. PROOF OF THEOREM 1.7

From the definitions of ν_1^ξ and ν_2^ξ in (1.29) and (1.34), it is immediate that $\text{supp}(\nu_1^\xi) \subset [0, \infty)$, $\int d\nu_1^\xi = 1$, $\text{supp}(\nu_2^\xi) \subset (-\infty, 0]$ and $\int d\nu_2^\xi = 1/2$. In fact, from (1.29) and the fact that the sets $\Gamma_1(s) = \text{supp}(\mu_1^s)$ are increasing as s increases (see Propositions 1.4 and 1.5) it follows that

$$(5.1) \quad \text{supp}(\nu_1^\xi) = \bigcup_{s \leq \xi} \Gamma_1(s) = \Gamma_1(\xi).$$

From (1.34) and the definition of σ in (1.36), it is then also clear that

$$\nu_2^\xi = \frac{1}{\xi} \int_0^\xi \mu_2^s ds \leq \frac{1}{\xi} \int_0^\infty \mu_2^s ds = \frac{1}{\xi} \sigma,$$

and

$$(5.2) \quad \sigma - \xi \nu_2^\xi = \int_\xi^\infty \mu_2^s ds$$

so that

$$(5.3) \quad \text{supp}(\sigma - \xi \nu_2^\xi) = \bigcup_{s \geq \xi} \Gamma_2(s) = \Gamma_2(\xi)$$

where the last equality holds since the sets $\Gamma_2(s)$ are decreasing as s increases, see also Propositions 1.4 and 1.5.

Thus in order to establish that (ν_1^ξ, ν_2^ξ) is the minimizer of the energy functional (1.37) under the conditions stated in Theorem 1.7 it suffices to prove that the variational conditions (1.38) and (1.39) are satisfied.

The proof of (1.38) and (1.39) will be carried out by integrating the variational conditions (1.32) and (1.33) with respect to s from 0 to ξ . The proof of Theorem 2.3 of [6] contains a more general expression for the variational conditions (1.32) and (1.33), which is valid for any complex number x , namely

$$(5.4) \quad 2 \int \log |x - y| d\mu_1^s(x) - \int \log |x - y| d\mu_2^s(x) - \ell^s = \log \left| \frac{z_1(x, s)}{z_2(x, s)} \right|,$$

$$(5.5) \quad 2 \int \log |x - y| d\mu_2^s(x) - \int \log |x - y| d\mu_1^s(x) = \log \left| \frac{z_2(x, s)}{z_3(x, s)} \right|.$$

These conditions reduce to (1.32) and (1.33) whenever $x \in \Gamma_1(s)$ and $x \in \Gamma_2(s)$, respectively.

Proof of (1.38). If we multiply both sides of (5.4) by $1/\xi$, integrate with respect to s from 0 to ξ , and interchange the order of integration, then we obtain

$$(5.6) \quad 2 \int \log |x - y| d\nu_1^\xi(x) - \int \log |x - y| d\nu_2^\xi(x) - \ell = \frac{1}{\xi} \int_0^\xi \log \left| \frac{z_1(x, s)}{z_2(x, s)} \right| ds, \quad x \in \mathbb{C},$$

for some constant $\ell \in \mathbb{R}$, where ν_1^ξ and ν_2^ξ are the measures defined in (1.29) and (1.34), respectively.

Let $x > 0$. Since $|z_1(x, s)| \geq |z_2(x, s)|$ for every s it follows from (5.6) that

$$(5.7) \quad 2 \int \log |x - y| d\nu_1^\xi(x) - \int \log |x - y| d\nu_2^\xi(x) - \ell \leq \frac{1}{\xi} \int_0^\infty \log \left| \frac{z_1(x, s)}{z_2(x, s)} \right| ds = \frac{1}{\xi} V(x).$$

If $x \in \text{supp}(\nu_1^\xi)$ then $x \in \Gamma_1(\xi)$ by (5.1) and therefore $x \in \Gamma_1(s)$ for every $s \geq \xi$, since the sets are increasing. Thus $|z_1(x, s)| = |z_2(x, s)|$ for every $s \geq \xi$, and equality holds in (5.7) for $x \in \text{supp}(\nu_1^\xi)$. This completes the proof of (1.38).

Proof of (1.39). If we multiply both sides of equation (5.5) by $1/\xi$, integrate with respect to s from 0 to ξ , and we interchange the order of integration we obtain

$$2 \int \log |x - y| d\nu_2^\xi(x) - \int \log |x - y| d\nu_1^\xi(x) = \frac{1}{\xi} \int_0^\xi \log \left| \frac{z_2(x, s)}{z_3(x, s)} \right| ds.$$

Since $|z_2(x, s)| \geq |z_3(x, s)|$ for every $s > 0$ it follows that

$$(5.8) \quad 2 \int \log |x - y| d\nu_2^\xi(x) - \int \log |x - y| d\nu_1^\xi(x) \geq 0, \quad x \in \mathbb{C}.$$

Equality holds in (5.8) if and only if $|z_2(x, s)| = |z_3(x, s)|$ for every $s \in (0, \xi]$, that is, if and only if

$$x \in \bigcap_{s \leq \xi} \Gamma_2(s) = \Gamma_2(\xi) = \text{supp}(\sigma - \xi \nu_2^\xi),$$

where the first equality holds since the sets $\Gamma_2(s)$ are decreasing as s increases, and the last equality holds because of (5.3). This completes the proof of (1.39). $\square$

6. PROOF OF THEOREM 1.8

Before starting with the proof of Theorem 1.8 we establish the following lemma.

Lemma 6.1. *Let $A_s(z)$ be given by (1.27), and let $z_1(x, s)$, $z_2(x, s)$ and $z_3(x, s)$ be the solutions of $A_s(z) = x$, ordered as in (1.15). Then*

$$(6.1) \quad \begin{aligned} \lim_{s \rightarrow 0+} z_1(x, s) &= x - pt(1-t) - a(1-t)^2, \\ \lim_{s \rightarrow 0+} s^{-1} z_2(x, s) &= -\frac{2at(1-t)^2}{2a(1-t) + pt - \sqrt{p^2 t^2 + 4ax}}, \\ \lim_{s \rightarrow 0+} s^{-1} z_3(x, s) &= -\frac{2at(1-t)^2}{2a(1-t) + pt - \sqrt{p^2 t^2 + 4ax}}. \end{aligned}$$

Proof. The lemma follows by a straightforward computation. $\square$

For the proof of Theorem 1.8 we need to establish the two identities (1.40) and (1.41).

Proof of (1.40). Let $x > 0$. From Propositions 1.4 and 1.5 it follows that there exist a unique $s^*(x) \geq 0$ so that for all $s > 0$

$$x \in \Gamma_1(s) \iff s \geq s^*(x).$$

Then $\log |z_1(x, s)/z_2(x, s)| = 0$ for all $s \geq s^*(x)$, and so by (1.35)

$$(6.2) \quad V(x) = \int_0^{s^*(x)} \log \left| \frac{z_1(x, s)}{z_2(x, s)} \right| ds.$$

There is a special value

$$x_0 = (1-t)(a(1-t) + pt) = \lim_{s \rightarrow 0+} \beta(s) = \lim_{s \rightarrow 0+} \gamma(s)$$

that belongs to every $\Gamma_1(s)$ for all $s > 0$. Then $s^*(x_0) = 0$ and

$$(6.3) \quad V(x_0) = 0.$$

The derivative of (6.2) is

$$(6.4) \quad V'(x) = \int_0^{s^*(x)} \left(\frac{1}{z_1(x, s)} \frac{\partial z_1(x, s)}{\partial x} - \frac{1}{z_2(x, s)} \frac{\partial z_2(x, s)}{\partial x} \right) ds.$$

In order to handle this integral we introduce new variables

$$(6.5) \quad \tilde{z}_1(x, s) = \frac{z_1(x, s)}{s}, \quad \tilde{z}_2(x, s) = \frac{z_2(x, s)}{s}, \quad \tilde{z}_3(x, s) = \frac{z_3(x, s)}{s}.$$

Since $z_j(x, s)$ for $j = 1, 2, 3$ is a solution of $A_s(z) = x$, it follows that $\tilde{z}_j(x, s)$ for $j = 1, 2, 3$ is a solution of the equation $B(z, s) = x$ where

$$(6.6) \quad B(z, s) = \frac{(sz + a(1-t)^2)(z + t(1-t))^2}{z^2} + \frac{pt(1-t)(z + t(1-t))}{z}.$$

Taking partial derivatives with respect to s and x on both sides of $B(\tilde{z}_j(x, s), s) = x$, and applying the chain rule, we obtain

$$(6.7) \quad \begin{aligned} \left(\frac{\partial B}{\partial z}(\tilde{z}_j(x, s), s) \right) \frac{\partial \tilde{z}_j(x, s)}{\partial s} + \frac{\partial B}{\partial s}(\tilde{z}_j(x, s), s) &= 0, \\ \left(\frac{\partial B}{\partial z}(\tilde{z}_j(x, s), s) \right) \frac{\partial \tilde{z}_j(x, s)}{\partial x} &= 1 \end{aligned}$$

for $j = 1, 2, 3$. From (6.6), it is elementary to deduce that

$$\frac{\partial B}{\partial s}(\tilde{z}_j(x, s), s) = \frac{(\tilde{z}_j(x, s) + t(1-t))^2}{\tilde{z}_j(x, s)}.$$

Combining this with (6.7) we obtain

$$(6.8) \quad \frac{1}{\tilde{z}_j(x, s)} \frac{\partial \tilde{z}_j(x, s)}{\partial x} = - \frac{1}{(\tilde{z}_j(x, s) + t(1-t))^2} \frac{\partial \tilde{z}_j(x, s)}{\partial s}, \quad j = 1, 2, 3.$$

Using (6.8) in (6.4) we get

$$V'(x) = - \int_0^{s^*(x)} \left(\frac{1}{(\tilde{z}_1(x, s) + t(1-t))^2} \frac{\partial \tilde{z}_1(x, s)}{\partial s} - \frac{1}{(\tilde{z}_2(x, s) + t(1-t))^2} \frac{\partial \tilde{z}_2(x, s)}{\partial s} \right) ds,$$

which can be written as

$$(6.9) \quad V'(x) = \int_0^{s^*(x)} \frac{\partial}{\partial s} (F(\tilde{z}_1(x, s)) - F(\tilde{z}_2(x, s))) ds$$

with

$$(6.10) \quad F(x) = \frac{1}{x + t(1-t)}.$$

From (6.9) and the fundamental theorem of calculus, we have

$$(6.11) \quad V'(x) = F(\tilde{z}_1(x, s^*(x))) - F(\tilde{z}_2(x, s^*(x))) - \lim_{s \rightarrow 0+} (F(\tilde{z}_1(x, s)) - F(\tilde{z}_2(x, s))).$$

By definition $s^*(x)$ is the smallest value of $s \geq 0$ for which $x \in \Gamma_1(s)$. Then $x = \gamma(s^*(x))$ if $x_0 < x$ and $x = \beta(s^*(x))$ if $0 < x < x_0$. We can observe from Figures 7-10 that $z_1(\gamma(s), s) = z_2(\gamma(s), s)$ and $z_1(\beta(s), s) = z_2(\beta(s), s)$. Therefore

$$\tilde{z}_1(x, s^*(x)) = \tilde{z}_2(x, s^*(x))$$

and (6.11) reduces because of (6.10) to

$$(6.12) \quad V'(x) = - \lim_{s \rightarrow 0+} \left(\frac{1}{\tilde{z}_1(x, s) + t(1-t)} - \frac{1}{\tilde{z}_2(x, s) + t(1-t)} \right).$$

From (6.5) and Lemma 6.1 we find that

$$\lim_{s \rightarrow 0+} \tilde{z}_1(x, s) = \infty \quad \text{and} \quad \lim_{s \rightarrow 0+} \tilde{z}_2(x, s) = - \frac{2at(1-t)^2}{2a(1-t) + pt - \sqrt{p^2t^2 + 4ax}}.$$

Then (6.12) leads by straightforward computation to

$$(6.13) \quad V'(x) = \frac{1}{t(1-t)} - \frac{2a}{t(\sqrt{p^2t^2 + 4ax} - pt)}.$$

We obtain $V(x)$ by integrating (6.13) with respect to x . Thus

$$V(x) = \frac{x}{t(1-t)} - \frac{\sqrt{p^2 t^2 + 4ax}}{t} - p \log(\sqrt{p^2 t^2 + 4ax} - pt) + C.$$

The constant of integration C should be such that $V(x_0) = 0$, see (6.3). This leads to

$$C = \frac{a(1-t)}{t} + p \log(2a(1-t))$$

and (1.40) is proved.

Proof of (1.41). The measure σ , introduced in (1.36), has the density

$$(6.14) \quad \frac{d\sigma(x)}{dx} = \int_0^\infty \frac{d\mu_2^s(x)}{dx} ds, \quad x < 0,$$

where $d\mu_2^s(x)/dx = 0$ for $x \notin \Gamma_2(s)$ and by (1.30)

$$\frac{d\mu_2^s(x)}{dx} = \frac{1}{2\pi i} \left(\frac{z'_{2-}(x, s)}{z_{2-}(x, s)} - \frac{z'_{2+}(x, s)}{z_{2+}(x, s)} \right) = \frac{1}{2\pi i} \left(\frac{z'_{3+}(x, s)}{z_{3+}(x, s)} - \frac{z'_{2+}(x, s)}{z_{2+}(x, s)} \right),$$

for $x \in \Gamma_2(s)$. The last equality comes from the fact that $z_{2-}(x, s) = z_{3+}(x, s)$ for $x \in \Gamma_2(s)$.

From Proposition 1.5 it follows that $d\mu_2^s(x)/dx = 0$ for every $x \in (-p^2 t^2/4a, 0]$ and every $s > 0$ so that

$$\frac{d\sigma(x)}{dx} = 0 \quad \text{for } x \in (-p^2 t^2/4a, 0].$$

Let $x < p^2 t^2/4a$. Again from Proposition 1.5 (or from Proposition 1.4 in case $p = 0$) it follows that there is a unique $s^*(x) > 0$ so that

$$x \in \Gamma_2(s) \quad \Longleftrightarrow \quad s \leq s^*(x).$$

Then $d\mu_2^s(x)/dx = 0$ for $s > s^*(x)$ so that (6.14) is in fact a finite integral

$$(6.15) \quad \frac{d\sigma(x)}{dx} = \frac{1}{2\pi i} \int_0^{s^*(x)} \left(\frac{1}{z_{3+}(x, s)} \frac{\partial z_{3+}(x, s)}{\partial x} - \frac{1}{z_{2+}(x, s)} \frac{\partial z_{2+}(x, s)}{\partial x} \right) ds.$$

The computation of (6.15) is similar to the computation of (6.4) given above. We use the functions $\tilde{z}_j(x, s)$ as in (6.5) and the function F as defined in (6.10). From (6.8) and (6.15) we then get

$$\begin{aligned} 2\pi i \frac{d\sigma(x)}{dx} &= - \int_0^{s^*(x)} \left(\frac{1}{(\tilde{z}_{3+} + t(1-t))^2} \frac{\partial \tilde{z}_{3+}}{\partial s} - \frac{1}{(\tilde{z}_{2+} + t(1-t))^2} \frac{\partial \tilde{z}_{2+}}{\partial s} \right) ds \\ &= F(\tilde{z}_{3+}(x, s^*(x))) - F(\tilde{z}_{2+}(x, s^*(x))) \\ &\quad - \lim_{s \rightarrow 0+} (F(\tilde{z}_{3+}(x, s)) - F(\tilde{z}_{2+}(x, s))) \\ (6.16) \quad &= - \lim_{s \rightarrow 0+} (F(\tilde{z}_{3+}(x, s)) - F(\tilde{z}_{2+}(x, s))) \end{aligned}$$

since $\tilde{z}_{2+}(x, s^*(x)) = \tilde{z}_{3+}(x, s^*(x))$.

Since $x < -p^2 t^2/4a$, we obtain from (6.5) and Lemma 6.1

$$\begin{aligned} \lim_{s \rightarrow 0+} \tilde{z}_2(x, s) &= \lim_{s \rightarrow 0+} s^{-1} z_2(x, s) = - \frac{2at(1-t)^2}{2a(1-t) + pt - i\sqrt{4a|x| - p^2 t^2}}, \\ \lim_{s \rightarrow 0+} \tilde{z}_3(x, s) &= \lim_{s \rightarrow 0+} s^{-1} z_3(x, s) = - \frac{2at(1-t)^2}{2a(1-t) + pt + i\sqrt{4a|x| - p^2 t^2}}. \end{aligned}$$

Using this and (6.10) in (6.16) we easily get

$$\begin{aligned} 2\pi i \frac{d\sigma(x)}{dx} &= - \lim_{s \rightarrow 0+} \left(\frac{1}{\tilde{z}_2(x, s) + t(1-t)} - \frac{1}{\tilde{z}_3(x, s) + t(1-t)} \right) \\ &= i \frac{\sqrt{4a|x| - p^2 t^2}}{t|x|}. \end{aligned}$$

which completes the proof of identity (1.41). $\square$
